The world population is growing in an exponential rate (Figure 1). There are many problems facing the growing world population. We as science educators have the obligation to help solve these problems.

- We must guarantee science education for all.
- We must avoid creating two separate social classes: one that is science literate, and another that is not.
- No single teaching method fits all.

Equal access to science education is a basic human right that belongs to all. Therefore, we must develop methods for teaching, learning, and assessing science, which will take into account the students' talents, interests, and cultural backgrounds [3]. If we will not develop this kind of curricula, we will form two class societies, divided not by royalty and wealth. These two societies would include one with people who have knowledge in science and technology, and can function in the new world, and another would be made up of people who do not have knowledge in science and technology. We must prevent this from happening by working hard on developing the right methods for teaching science.
With these new methods, students move from a passive mode of learning, which is teacher centered (Figure 2), to an active mode of learning, which is student centered (Figure 3).

In order to make the science class relevant to the students’ lives and environment, every class from grade five to university starts with a report on a scientific issue that they find in the daily newspaper, magazine, or online. Students are asked to summarize the article and present it to the class in a one-minute presentation. In each class the teachers select a group of students to report to the class. This guarantees that the whole class is coming prepared.

We must emphasize to the students:
- That a basic science background is needed to understand the article.
- That science is part of everyday life.
- That it is important to communicate science accurately.

This exercise helps the students to get into the habit of reading articles about science in newspapers, magazines, and online. This also encourages them to listen to science programs on radio and television. Many times students who graduated come back to say that they are still reading scientific articles, but are lacking a platform to report and discuss these articles. Usually the discussion in class is very lively. It is easy to relate the subject of the day to one of the articles represented. For example, an article on nuclear technology can be a start point for discussing nuclear power plants, nuclear weapons, fission reaction, the nucleus of the atom, and the structure of the atom as a whole. This way students realize that their science class has relevance to their life and is not just a hard class that they have to take.

### Student Projects

A requirement in the science class is that students show their knowledge and understanding of the concept discussed through any mediums of their choice [4]. For example [7], the concept of the chemical bond is presented through a drama parodying the popular movie, “The Godfather,” but called “The Bondfather” and featuring a mother begging the Bondfather, Don Mendeleev, to break up the bond between her daughter, Chlorine, and her boyfriend, Sodium. The mother says she is afraid that their relationship will be broken in water and she would like her daughter to be in a covalent bond, where she can share electrons with her partner and have a strong bond with them. The same concept is presented by another drama called “Love Story Between Sodium and Chlorine,” following Shakespeare’s “Romeo and Juliet.” Dance students choreographed a dance on the bond between Sodium and Chlorine. They performed this dance in many venues as shown in Figure 5.

Students produce all their scientific visualizations as seen in Figure 6. Nothing is commercially produced. Students use their talents, interests, and cultural backgrounds as tools to help visualize scientific concepts [5, 6].
Many times the projects are the result of teamwork to resemble the reality of the workplace. It is extremely important that students learn to work in teams and not just as individuals. Once they are in the workplace, they will have to be part of a team. Figure 7 shows a student’s description on teamwork.

Many television studios reported on a project produced by seventh grade students who represented the depletion of the ozone layer through dance. The reporters interviewed the students and were amazed on how well they understood the concept after performing their dance (Figure 8). This was shown on television in South Africa, China, WGN, ABC, NBC, and CNN television broadcasts.

One of the student dancers, when interviewed by CNN, said the following statement (Figure 9): “After I was on stage… My cousin played one of the atoms. And she was splitting them and everything and I was like ‘oh, that’s how that works.’ I never knew nothing about it until I did the dance.”

It is extremely important in the lower grades to involve the parents in understanding the science that their children learn so they can encourage them at home to pursue their studies. Therefore, it is important to conduct separate workshops for parents, teachers, and students and subsequently, combine the groups together. In the workshops, parents and teachers learn how to use art, music, dance, and drama in order to understand scientific concepts, and how to use household materials to perform science experiments which they could replicate in their own kitchens. In Figure 11 a mother and daughter are working together in their workshop.

Results

For five years teachers and students were evaluated after attending the workshops. In each school there was a class where
teachers and students participated in the workshop, and a control class where the teachers and students did not participate.

The following graphs show the results of testing hundreds of teachers and parents, and thousands of students, comparing them to the control group.

As seen in Figure 12, the percentage of teachers who felt that they could teach science was 0% before the workshop. After the workshop, 36% felt very capable in teaching science.

As seen in Figure 13, there is a huge difference in achievement by students whose teachers and parents participated in the workshops, and children from the control group. The fifth grade and the eighth grade are very important grades in Chicago and other places in the U.S. After fifth grade students move from elementary school to middle school, and after eighth grade students move from middle school to high school.

These methods of teaching and learning fulfills my tenet in life, which prompted the creation of these methods – that equal access to science education is a human right that belongs to all.
